Assignment 6: GLMs (Linear Regressios, ANOVA, & t-tests)

Lehe, Xu

OVERVIEW

This exercise accompanies the lessons in Environmental Data Analytics on generalized linear models.

Directions

- 1. Change "Student Name" on line 3 (above) with your name.
- 2. Work through the steps, **creating code and output** that fulfill each instruction.
- 3. Be sure to **answer the questions** in this assignment document.
- 4. When you have completed the assignment, **Knit** the text and code into a single PDF file.
- 5. After Knitting, submit the completed exercise (PDF file) to the dropbox in Sakai. Add your last name into the file name (e.g., "Fay_A06_GLMs.Rmd") prior to submission.

The completed exercise is due on Monday, February 28 at 7:00 pm.

Set up your session

- 1. Set up your session. Check your working directory. Load the tidyverse, agricolae and other needed packages. Import the *raw* NTL-LTER raw data file for chemistry/physics (NTL-LTER_Lake_ChemistryPhysics_Raw.csv). Set date columns to date objects.
- 2. Build a ggplot theme and set it as your default theme.

Simple regression

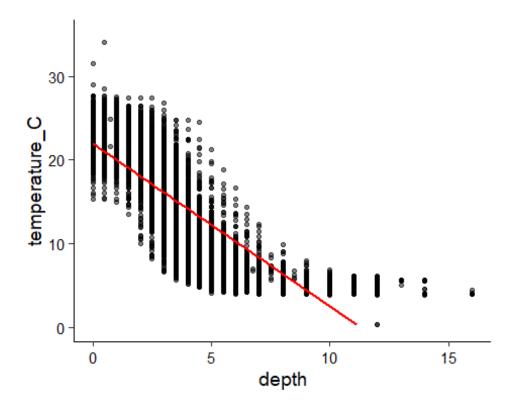

Our first research question is: Does mean lake temperature recorded during July change with depth across all lakes?

3. State the null and alternative hypotheses for this question:

```
>Answer: H0: \beta1 = 0, Ha: \beta1 \neq 0
```

- 4. Wrangle your NTL-LTER dataset with a pipe function so that the records meet the following criteria:
- Only dates in July.
- Only the columns: lakename, year4, daynum, depth, temperature_C
- Only complete cases (i.e., remove NAs)
- 5. Visualize the relationship among the two continuous variables with a scatter plot of temperature by depth. Add a smoothed line showing the linear model, and limit temperature values from 0 to 35 $^{\circ}$ C. Make this plot look pretty and easy to read.

```
#4
library(lubridate)
##
## 载入程辑包: 'lubridate'
## The following objects are masked from 'package:base':
##
       date, intersect, setdiff, union
##
NTL$sampledate <- as.Date(NTL$sampledate, format = "%m/%d/%y")
July<-
 NTL %>%
 filter(month(sampledate) == 07) %>%
  select(lakename, year4, daynum, depth, temperature C) %>%
  filter(!is.na(temperature_C))
  view(July)
#5
```

6. Interpret the figure. What does it suggest with regards to the response of temperature to depth? Do the distribution of points suggest about anything about the linearity of this trend?

Answer: Depth and temperature has relationship. The linearity may exist when the depth is shallow. When the depth get larger it is hard to say the linearity still exist, more data should be provided to examine the linearity. Logarithm may describe their relationship better. But, in the depth between 0-7, depth and temeperature have a trend of linearity.

Perform a linear regression to test the relationship and display the results

```
#7
temdepth <- lm(data = July, temperature_C ~ depth)</pre>
summary(temdepth)
##
## Call:
## lm(formula = temperature_C ~ depth, data = July)
## Residuals:
##
       Min
                10 Median
                                30
                                       Max
## -9.5173 -3.0192 0.0633 2.9365 13.5834
##
## Coefficients:
               Estimate Std. Error t value Pr(>|t|)
##
## (Intercept) 21.95597   0.06792   323.3   <2e-16 ***
## depth
             -1.94621
                           0.01174 -165.8
                                             <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 3.835 on 9726 degrees of freedom
## Multiple R-squared: 0.7387, Adjusted R-squared: 0.7387
## F-statistic: 2.75e+04 on 1 and 9726 DF, p-value: < 2.2e-16
```

8. Interpret your model results in words. Include how much of the variability in temperature is explained by changes in depth, the degrees of freedom on which this finding is based, and the statistical significance of the result. Also mention how much temperature is predicted to change for every 1m change in depth.

Answer: 73.87% of the variability in temperature is explained by changes in depth, the degrees of freedom is 9726, the statistical significance is 2e- 16 < 0.001, therefore, $\beta 1 \neq 0$, we reject null hypothesis. For every meter change in depth, temperature may decrease 1.94621 celsius degree.

Multiple regression

Let's tackle a similar question from a different approach. Here, we want to explore what might be the best set of predictors for lake temperature in July across the monitoring period at the North Temperate Lakes LTER.

- 9. Run an AIC to determine what set of explanatory variables (year4, daynum, depth) is best suited to predict temperature.
- 10. Run a multiple regression on the recommended set of variables.

```
#9
temAIC <- lm(data = July, temperature_C ~ depth + year4 +
daynum)
```

```
step(temAIC)
## Start: AIC=26065.53
## temperature C ~ depth + year4 + daynum
##
##
            Df Sum of Sq
                            RSS
                                 AIC
## <none>
                         141687 26066
## - year4
            1
                    101 141788 26070
## - daynum 1
                   1237 142924 26148
## - depth
            1
                 404475 546161 39189
##
## Call:
## lm(formula = temperature_C ~ depth + year4 + daynum, data = July)
## Coefficients:
## (Intercept)
                      depth
                                              daynum
                                  year4
      -8.57556
                   -1.94644
                                0.01134
                                             0.03978
#so the best set of explanatory variables are year4, daynum, and depth.
#10
temAIC <- lm(data = July, temperature_C ~ depth + year4 +
              daynum)
summary(temAIC)
##
## Call:

## F-statistic: 9283 on 3 and 9724 DF, p-value: < 2.2e-16
```

11. What is the final set of explanatory variables that the AIC method suggests we use to predict temperature in our multiple regression? How much of the observed variance does this model explain? Is this an improvement over the model using only depth as the explanatory variable?

Answer: The best set of explanatory variables are year4, daynum, and depth. This model explains 74.11% observed variance. Yes, only using depth only explains 73.87% of the variability in temperature. Now, it increases to 74.11%.

Analysis of Variance

12. Now we want to see whether the different lakes have, on average, different temperatures in the month of July. Run an ANOVA test to complete this analysis. (No need to test assumptions of normality or similar variances.) Create two sets of models: one expressed as an ANOVA models and another expressed as a linear model (as done in our lessons).

```

```

13. Is there a significant difference in mean temperature among the lakes? Report your findings.

Answer: pr=2e-16<0.001, so we reject null hypothesis. The difference between at least a pair of lakes' temperature means is statiscally significant.

14. Create a graph that depicts temperature by depth, with a separate color for each lake. Add a geom_smooth (method = "lm", se = FALSE) for each lake. Make your points 50 % transparent. Adjust your y axis limits to go from 0 to 35 degrees. Clean up your graph to make it pretty.

15. Use the Tukey's HSD test to determine which lakes have different means.

```

16.From the findings above, which lakes have the same mean temperature, statistically speaking, as Peter Lake? Does any lake have a mean temperature that is statistically distinct from all the other lakes?

Answer: Ward Lake and Paul Lake. There is no one lake that has a mean temperature statistically distinct from all the other lakes.

17. If we were just looking at Peter Lake and Paul Lake. What's another test we might explore to see whether they have distinct mean temperatures?

Answer: We can use two-sample T-test to explore.
